ABSTRACT OF THE DISCLOSURE

2

1

3 An analyzer apparatus includes a receptacle for an ampoule, 4 an analysis system, an incubator, and a master control. 5 analysis system includes a light source and a photodetector positioned such that the light from the light source passes 6 7 through the receptacle. The master control includes a display, a 8 timer, and a memory provided with a look-up table. During 9 operation, an ampoule containing a sample and an indicator which 10 changes color when a certain level of biological activity is 11 present in the sample is placed within the receptacles. 12 analysis system is operated to transmit light at the predetermined 13 wavelength through the ampoule to the detector, and a maximum 14 amount of light passing through the ampoule is logged. 15 incubator is operated to heat the receptacle and the ampoule 16 therein to a desired test temperature and the timer is started. 17 The analysis system periodically transmits light through the 18 ampoule. Increased biological activity in the ampoule causes a 19 color change in the indicator which reduces light transmission 20 through the ampoule. When the light detected is reduced relative 21 to the light transmitted by a predetermined percentage of the 22 maximum amount of light, the master control signals that the test 23 is complete. Based on the amount of time required for this to 24 occur, the master control determines from the look-up table the 25 bacterial content in the sample at the start of the test.
